Box models

Divide people into categories:

▲□▶ ▲□▶ ▲□▶ ▲□▶ = 三 のへで

▶ Susceptible \rightarrow Infectious \rightarrow Recovered

What determines transition rates?

▲□▶ ▲□▶ ▲□▶ ▲□▶ = 三 のへで

- People get better independently
- People get infected by infectious people

Conceptual modeling

Conceptual modeling

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 のへで

- What is the final result?
- When does disease increase, decrease?

Implementation

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

- The conceptually *simplest* way to implement this conceptual model concretely is Ordinary Differential Equations (ODEs)
 - Other options may be more realistic
 - Or simpler in practice
- Requires assumption about recovery and transmission

Recovery

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 のへで

- Total recovery rate is γI
- Mean time infectious is $D = 1/\gamma$

Transmission

- Susceptible people get infected by:
 - Going around and contacting people (rate *c*)
 - Some of these people are infectious (proportion I/N)
 - Some of these contacts are effective (proportion p)
- Per capita rate of becoming infected is cpI/N. We write $\beta I/N$ ($\beta = cp$)
- Population-level transmission rate is $\beta SI/N$

Another perspective on transmission

- Infectious people infect others by:
 - Going around and contacting people (rate *c*)
 - Some of these people are susceptible (proportion S/N)
 - Some of these contacts are effective (proportion *p*)
- Per capita rate of infecting others is cpS/N. We write $\beta S/N$
- Population-level transmission rate is \(\beta SI/N\)

ODE implementation

More about transmission

- ▶ β = pc
- Sometimes this decomposition is clear

▲□▶ ▲□▶ ▲□▶ ▲□▶ = 三 のへで

But usually it's not

Population sizes

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ● □ ● ● ●

Population sizes

$$\begin{aligned} \frac{dS}{dt} &= -\beta(N)\frac{SI}{N} \\ \frac{dI}{dt} &= \beta(N)\frac{SI}{N} - \gamma I \\ \frac{dR}{dt} &= \gamma I \end{aligned}$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Standard incidence

Standard incidence

• $\beta(N) = \beta_0$ • $\mathcal{T} = \frac{\beta_0 SI}{N}$

Also known as frequency-dependent transmission

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Mass action

$$\blacktriangleright \beta(N) = \beta_1 N$$

$$\blacktriangleright \mathcal{T} = \beta_1 SI$$

Also known as density-dependent transmission

Other

・ロン ・ 四 と ・ 回 と ・ 回 と

æ

- May not go to zero when N does
- May not go to ∞ when N does

Digression – units

- $\mathcal{T} = \beta SI/N$: [ppl/time]
- ▶ β : [1/time]
 - $\blacktriangleright \ \beta/\gamma = \beta D : [1]$
 - Standard incidence, $\beta_0 : [1/time]$
 - Mass-action incidence, $\beta_0 : [1/time]$

Summary

- Dynamics are an esssential tool to link scales
- Very simple models can provide useful insights
- More complex models can provide more detail, but also require more assumptions, and more choices

(ロ) (同) (三) (三) (三) (三) (○) (○)

Conclusions from simple models

- Threshold behaviour
- Tendency to oscillate
